Finals Week: June 6th-10th, 2016.
Min-Norm Point: Definition

- Consider the optimization:

\[
\begin{align*}
\text{minimize} & \quad \|x\|_2^2 \\
\text{subject to} & \quad x \in B_f
\end{align*}
\]

where \( B_f \) is the base polytope of submodular \( f \), and
\[
\|x\|_2^2 = \sum_{e \in E} x(e)^2
\]

is the squared 2-norm. Let \( x^* \) be the optimal solution.

- Note, \( x^* \) is the unique optimal solution since we have a strictly convex objective over a set of convex constraints.

- \( x^* \) is called the minimum norm point of the base polytope.

Min-Norm Point: Examples
Min-Norm Point and Submodular Function Minimization

- Given optimal solution $x^*$ to the above, consider the quantities

  $y^* = x^* \land 0 = (\min(x^*(e), 0) | e \in E)$ \hfill (18.1)
  $A_- = \{e : x^*(e) < 0\}$ \hfill (18.2)
  $A_0 = \{e : x^*(e) \leq 0\}$ \hfill (18.3)

- Thus, we immediately have that:

  $A_- \subseteq A_0$ \hfill (18.4)

  and that

  $x^*(A_-) = x^*(A_0) = y^*(A_-) = y^*(A_0)$ \hfill (18.5)

- It turns out, these quantities will solve the submodular function minimization problem, as we now show.

- The proof is nice since it uses the tools we’ve been recently developing.

A polymatroid function’s polyhedron is a polymatroid.

**Theorem 18.2.1**

Let $f$ be a submodular function defined on subsets of $E$. For any $x \in \mathbb{R}^E$, we have:

$$rank(x) = \max \{y(E) : y \leq x, y \in P_f\} = \min \{x(A) + f(E \setminus A) : A \subseteq E\}$$ \hfill (18.1)

Essentially the same theorem as Theorem ??, but note $P_f$ rather than $P_f^+$. Taking $x = 0$ we get:

**Corollary 18.2.2**

Let $f$ be a submodular function defined on subsets of $E$. We have:

$$rank(0) = \max \{y(E) : y \leq 0, y \in P_f\} = \min \{f(A) : A \subseteq E\}$$ \hfill (18.2)
Summary of sat, and dep

- For $x \in P_f$, $\text{sat}(x)$ (span, closure) is the maximal saturated ($x$-tight) set w.r.t. $x$. I.e., $\text{sat}(x) = \{e : e \in E, \forall \alpha > 0, x + \alpha 1_e \notin P_f\}$. That is,
  \begin{equation}
  \text{cl}(x) \overset{\text{def}}{=} \text{sat}(x) \triangleq \bigcup \{A : A \in D(x)\} = \bigcup \{A : A \subseteq E, x(A) = f(A)\} = \{e : e \in E, \forall \alpha > 0, x + \alpha 1_e \notin P_f\}
  \end{equation}

- For $e \in \text{sat}(x)$, we have $\text{dep}(x,e) \subseteq \text{sat}(x)$ (fundamental circuit) is the minimal (common) saturated ($x$-tight) set w.r.t. $x$ containing $e$. I.e.,
  \begin{equation}
  \text{dep}(x,e) = \begin{cases} 
  \bigcap \{A : e \in A \subseteq E, x(A) = f(A)\} & \text{if } e \in \text{sat}(x) \\
  \emptyset & \text{else}
  \end{cases}
  \end{equation}
  \begin{equation}
  = \{e' : \exists \alpha > 0, \text{ s.t. } x + \alpha (1_e - 1_{e'}) \in P_f\}
  \end{equation}
  Note, if $x + \alpha (1_e - 1_{e'}) \in P_f$, then $x + \alpha' (1_e - 1_{e'}) \in P_f$ for any $0 \leq \alpha' < \alpha$.

Summary important definitions so far: tight, dep, & sat

- $x$-tight sets: For $x \in P_f$, $D(x) \overset{\text{def}}{=} \{A \subseteq E : x(A) = f(A)\}$.
- Polymatroid closure/maximal $x$-tight set: For $x \in P_f$, $\text{sat}(x) \overset{\text{def}}{=} \{e : e \in E, \forall \alpha > 0, x + \alpha 1_e \notin P_f\}$.
- Saturation capacity: for $x \in P_f$, $0 \leq \check{c}(x;e) \overset{\text{def}}{=} \min \{f(A) - x(A) | \forall A \ni e\} = \max \{\alpha : \alpha \in \mathbb{R}, x + \alpha 1_e \in P_f\}$.
- Recall: $\text{sat}(x) = \{e : \check{c}(x;e) = 0\}$ and $E \setminus \text{sat}(x) = \{e : \check{c}(x;e) > 0\}$.
- $e$-containing $x$-tight sets: For $x \in P_f$, $D(x,e) = \{A : e \in A \subseteq E, x(A) = f(A)\} \subseteq D(x)$.
- Minimal $e$-containing $x$-tight set/polymatroidal fundamental circuit/: For $x \in P_f$, $\text{dep}(x,e) = \begin{cases} 
  \bigcap \{A : e \in A \subseteq E, x(A) = f(A)\} & \text{if } e \in \text{sat}(x) \\
  \emptyset & \text{else}
  \end{cases}
  \begin{equation}
  = \{e' : \exists \alpha > 0, \text{ s.t. } x + \alpha (1_e - 1_{e'}) \in P_f\}
  \end{equation}$
Proof that min-norm gives optimal Lovász extension

Min-Norm Point and SFM

**Theorem 18.3.1**

Let $y^*$, $A_-$, and $A_0$ be as given. Then $y^*$ is a maximizer of the l.h.s. of Eqn. (17.7). Moreover, $A_-$ is the unique minimal minimizer of $f$ and $A_0$ is the unique maximal minimizer of $f$.

**Proof.**

First note, since $x^* \in B_f$, we have $x^*(E) = f(E)$, meaning $\text{sat}(x^*) = E$. Thus, we can consider any $e \in E$ within $\text{dep}(x^*, e)$.

Consider any pair $(e, e')$ with $e' \in \text{dep}(x^*, e)$ and $e \in A_-$. Then $x^*(e) < 0$, and $\exists \alpha > 0$ s.t. $x^* + \alpha 1_e - \alpha 1_{e'} \in P_f$.

We have $x^*(E) = f(E)$ and $x^*$ is minimum in $l_2$ sense. We have $(x^* + \alpha 1_e - \alpha 1_{e'}) \in P_f$, and in fact

$$
(x^* + \alpha 1_e - \alpha 1_{e'})(E) = x^*(E) + \alpha - \alpha = f(E) \quad (18.1)
$$

so $x^* + \alpha 1_e - \alpha 1_{e'} \in B_f$ also.

Minimality of $x^* \in B_f$ in $l_2$ sense requires that, with such an $\alpha > 0$,

$$
(x^*(e))^2 + (x^*(e'))^2 < (x^*_{\text{new}}(e))^2 + (x^*_{\text{new}}(e'))^2
$$

Given that $e \in A_-$, $x^*(e) < 0$. Thus, if $x^*(e') > 0$, we could have $(x^*(e) + \alpha)^2 + (x^*(e') - \alpha)^2 < (x^*(e))^2 + (x^*(e'))^2$, contradicting the optimality of $x^*$.

If $x^*(e') = 0$, we would have $(x^*(e) + \alpha)^2 + (\alpha)^2 < (x^*(e))^2$, for any $0 < \alpha < |x^*(e)|$ (Exercise:), again contradicting the optimality of $x^*$.

Thus, we must have $x^*(e') < 0$ (strict negativity).
Proof that min-norm gives optimal Lovász extension

Min-Norm Point and SFM

... proof of Thm. 18.3.1 cont.

Thus, for a pair \((e, e')\) with \(e' \in \text{dep}(x^*, e)\) and \(e \in A_\_\), we have \(x(e') < 0\) and hence \(e' \in A_\_'\).

Hence, \(\forall e \in A_\_\), we have \(\text{dep}(x^*, e) \subseteq A_\_'\).

A very similar argument can show that, \(\forall e \in A_0\), we have \(\text{dep}(x^*, e) \subseteq A_0\).

Also, recall that \(e \in \text{dep}(x^*, e)\).

Therefore, we have \(\bigcup_{e \in A_\_} \text{dep}(x^*, e) = A_\_\) and \(\bigcup_{e \in A_0} \text{dep}(x^*, e) = A_0\).

i.e., \(\{\text{dep}(x^*, e)\}_{e \in A_\_}\) is cover for \(A_\_\), as is \(\{\text{dep}(x^*, e)\}_{e \in A_0}\) for \(A_0\).

\(\text{dep}(x^*, e)\) is minimal tight set containing \(e\), meaning \(x^*(\text{dep}(x^*, e)) = f(\text{dep}(x^*, e))\), and since tight sets are closed under union, we have that \(A_\_\) and \(A_0\) are also tight, meaning:

\[
x^*(A_\_) = f(A_\_) \quad (18.2)
\]

\[
x^*(A_0) = f(A_0) \quad (18.3)
\]

\[
x^*(A_\_) = x^*(A_0) = y^*(E) = y^*(A_0) + y^*(E \setminus A_0) \quad (18.4)
\]

and therefore, all together we have

\[
f(A_\_) = f(A_0) = x^*(A_\_) = x^*(A_0) = y^*(E) \quad (18.5)
\]
Proof that min-norm gives optimal Lovász extension

Min-Norm Point and SFM

... proof of Thm. 18.3.1 cont.

- Now, \( y^* \) is feasible for the l.h.s. of Eqn. (17.7) (recall, which is \( \max \{ y(E) | y \in P_f, y \leq 0 \} = \min \{ f(X) | X \subseteq V \} \)). This follows since, we have \( y^* = x^* \land 0 \leq 0 \), and since \( x^* \in B_f \subseteq P_f \), and \( y^* \leq x^* \) and \( P_f \) is down-closed, we have that \( y^* \in P_f \).

- Also, for any \( y \in P_f \) with \( y \leq 0 \) and for any \( X \subseteq E \), we have \( y(E) \leq y(X) \leq f(X) \).

- Hence, we have found a feasible for l.h.s. of Eqn. (17.7), \( y^* \leq 0 \), \( y^* \in P_f \), so \( y^*(E) \leq f(X) \) for all \( X \).

- So \( y^*(E) \leq \min \{ f(X) | X \subseteq V \} \).

- Considering Eqn. (18.6), we have found sets \( A_- \) and \( A_0 \) with tightness in Eqn. (17.7), meaning \( y^*(E) = f(A_-) = f(A_0) \).

- Hence, \( y^* \) is a maximizer of l.h.s. of Eqn. (17.7), and \( A_- \) and \( A_0 \) are minimizers of \( f \).

Now, for any \( X \subseteq A_- \), we have

\[
f(X) \geq x^*(X) > x^*(A_-) = f(A_-)
\]  
(18.6)

And for any \( X \supset A_0 \), we have

\[
f(X) \geq x^*(X) > x^*(A_0) = f(A_0)
\]  
(18.7)

Hence, \( A_- \) must be the unique minimal minimizer of \( f \), and \( A_0 \) is the unique maximal minimizer of \( f \).
Min-Norm Point and SFM

- So, if we have a procedure to compute the min-norm point computation, we can solve SFM.
- Nice thing about previous proof is that it uses both expressions for \( \text{dep} \) for different purposes.
- This was discovered by Fujishige (in fact the proof above is an expanded version of the one found in the book).
- As we saw last time, the algorithm (by F. Wolfe) can find this min-norm point, essentially an active-set procedure for quadratic programming. It uses Edmonds’s greedy algorithm to make it efficient.
- This is currently the best practical algorithm for general purpose submodular function minimization.
- But recall, its underlying lower-bound complexity is unknown.

---

Min-norm point and other minimizers of \( f \)

- Recall, that the set of minimizers of \( f \) forms a lattice.
- In fact, with \( x^* \) the min-norm point, and \( A_- \) and \( A_0 \) as defined above, we have the following theorem:

**Theorem 18.3.2**

Let \( A \subseteq E \) be any minimizer of submodular \( f \), and let \( x^* \) be the minimum-norm point. Then \( A \) can be expressed in the form:

\[
A = A_- \cup \bigcup_{a \in A_m} \text{dep}(x^*, a)
\]

(18.8)

for some set \( A_m \subseteq A_0 \setminus A_- \). Conversely, for any set \( A_m \subseteq A_0 \setminus A_- \), then \( A \triangleq A_- \cup \bigcup_{a \in A_m} \text{dep}(x^*, a) \) is a minimizer.
Min-norm point and other minimizers of $f$

**proof of Thm. 18.3.2.**

- If $A$ is a minimizer, then $A_0 \subseteq A \subseteq A_0$, and $f(A) = y^*(E)$ is the minimum valuation of $f$.
- But $x^* \in P_f$, so $x^*(A) \leq f(A)$ and $f(A) = x^*(A_0) \leq x^*(A)$ (or alternatively, just note that $x^*(A_0 \setminus A) = 0$).
- Hence, $x^*(A) = x^*(A_0) = f(A)$ so that $A$ is also a tight set for $x^*$.
- For any $a \in A$, $A$ is a tight set containing $a$, and $\text{dep}(x^*, a)$ is the minimal tight containing $a$.
- Hence, for any $a \in A$, $\text{dep}(x^*, a) \subseteq A$.
- This means that $\bigcup_{a \in A} \text{dep}(x^*, a) = A$.
- Since $A_0 \subseteq A \subseteq A_0$, then $\exists A_m \subseteq A \setminus A_0$ such that
  
  $$A = \bigcup_{a \in A_0} \text{dep}(x^*, a) \cup \bigcup_{a \in A_m} \text{dep}(x^*, a) = A_0 \cup \bigcup_{a \in A_m} \text{dep}(x^*, a)$$

Then since $A$ is a union of tight sets, $A$ is also a tight set, and we have $f(A) = x^*(A)$.
- But $x^*(A \setminus A_0) = 0$, so $f(A) = x^*(A) = x^*(A_0) = f(A_0)$ meaning $A$ is also a minimizer of $f$.

Therefore, we can generate the entire lattice of minimizers of $f$ starting from $A_0$ and $A_0$ given access to $\text{dep}(x^*, e)$. 
On a unique minimizer $f$

- Note that if $f(e|A) > 0$, $\forall A \subseteq E$ and $e \in E \setminus A$, then we have $A_\perp = A_0$ (there is one unique minimizer).
- On the other hand, if $A_\perp = A_0$, it does not imply $f(e|A) > 0$ for all $A \subseteq E \setminus \{e\}$.
- If $A_\perp = A_0$ then certainly $f(e|A_0) > 0$ for $e \in E \setminus A_0$ and $-f(e|A_0 \setminus \{e\}) > 0$ for all $e \in A_0$.

Duality: convex minimization of L.E. and min-norm alg.

- Let $f$ be a submodular function with $\tilde{f}$ it’s Lovász extension. Then the following two problems are duals (Bach-2013):
  \[
  \begin{align*}
  \text{minimize} & \quad \tilde{f}(w) + \frac{1}{2} \|w\|_2^2 \quad (18.10) \\
  \text{subject to} & \quad x \in B_f \quad (18.11a)
  \end{align*}
  \]
  where $B_f = P_f \cap \{x \in \mathbb{R}^V : x(V) = f(V)\}$ is the base polytope of submodular function $f$, and $\|x\|_2^2 = \sum_{e \in V} x(e)^2$ is squared 2-norm.
- Equation (18.10) is related to proximal methods to minimize the Lovász extension (see Parikh&Boyd, “Proximal Algorithms” 2013).
- Equation (18.11b) is solved by the minimum-norm point algorithm (Wolfe-1976, Fujishige-1984, Fujishige-2005, Fujishige-2011) is (as we will see) essentially an active-set procedure for quadratic programming, and uses Edmonds’s greedy algorithm to make it efficient.
- Unknown worst-case running time, although in practice it usually performs quite well (see below).
Proof that min-norm gives optimal

Lovász extension

Choquet Integration

Review

The next slide comes from lecture 13.

Polymatroidal polyhedron and greedy

Thus, restating the above results into a single complete theorem, we have a result very similar to what we saw for matroids (i.e., Theorem ??)

**Theorem 18.4.1**

If \( f : 2^E \rightarrow \mathbb{R}_+ \) is given, and \( P \) is a polytope in \( \mathbb{R}_+^E \) of the form

\[
P = \{ x \in \mathbb{R}_+^E : x(A) \leq f(A), \forall A \subseteq E \},
\]

then the greedy solution to the problem \( \max( wx : x \in P ) \) is \( \forall w \) optimum iff \( f \) is monotone non-decreasing submodular (i.e., iff \( P \) is a polymatroid).
Optimization over $P_f$

- Consider the following optimization. Given $w \in \mathbb{R}^E$,

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in P_f
\end{align*} \quad (18.12a)$$

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in P_f
\end{align*} \quad (18.12b)$$

- Since $P_f$ is down closed, if $\exists e \in E$ with $w(e) < 0$ then the solution above is unboundedly large. Hence, assume $w \in \mathbb{R}^E_+$.  

- The greedy algorithm will solve this, and the proof almost identical.

- Due to Theorem ??, any $x \in P_f$ with $x \notin B_f$ is dominated by $x \leq y \in B_f$ which can only increase $w^\top x \leq w^\top y$.

- Hence, the problem is equivalent to: given $w \in \mathbb{R}^E_+$,

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in B_f
\end{align*} \quad (18.13a)$$

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in B_f
\end{align*} \quad (18.13b)$$

- Moreover, we can have $w \in \mathbb{R}^E$ if we insist on $x \in B_f$.

A continuous extension of $f$

- Consider again optimization problem. Given $w \in \mathbb{R}^E$,

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in B_f
\end{align*} \quad (18.14a)$$

$$\begin{align*}
\text{maximize} & \quad w^\top x \\
\text{subject to} & \quad x \in B_f
\end{align*} \quad (18.14b)$$

- We may consider this optimization problem a function $\tilde{f} : \mathbb{R}^E \to \mathbb{R}$ of $w \in \mathbb{R}^E$, defined as:

$$\tilde{f}(w) = \max(wx : x \in B_f) \quad (18.15)$$

- Hence, for any $w$, from the solution to the above theorem (as we have seen), we can compute the value of this function using Edmond’s greedy algorithm.
A continuous extension of submodular $f$

- That is, given a submodular function $f$, a $w \in \mathbb{R}^E$, choose element order $(e_1, e_2, \ldots, e_m)$ based on decreasing $w$, so that $w(e_1) \geq w(e_2) \geq \cdots \geq w(e_m)$.

- Define the chain with $i^{th}$ element $E_i = \{e_1, e_2, \ldots, e_i\}$, we have
  \[
  \tilde{f}(w) = \max(wx : x \in P_f) = \sum_{i=1}^{m} w(e_i) f(e_{i|E_{i-1}})
  \]
  \[
  = \sum_{i=1}^{m} w(e_i)(f(E_i) - f(E_{i-1}))
  \]
  \[
  = w(e_m)f(E_m) + \sum_{i=1}^{m-1} (w(e_i) - w(e_{i+1}))f(E_i)
  \]

- We say that $\emptyset \triangleq E_0 \subset E_1 \subset E_2 \subset \cdots \subset E_m = E$ forms a chain based on $w$.

---

Definition of the continuous extension, once again, for reference:

\[
\tilde{f}(w) = \max(wx : x \in B_f)
\]  

Therefore, if $f$ is a submodular function, we can write

\[
\tilde{f}(w) = w(e_m)f(E_m) + \sum_{i=1}^{m-1} (w(e_i) - w(e_{i+1}))f(E_i)
\]

\[
= \sum_{i=1}^{m} \lambda_i f(E_i)
\]

where $\lambda_m = w(e_m)$ and otherwise $\lambda_i = w(e_i) - w(e_{i+1})$, where the elements are sorted descending according to $w$ as before.

- From convex analysis, we know $\tilde{f}(w) = \max(wx : x \in P)$ is always convex in $w$ for any set $P \subseteq \mathbb{R}^E$, since it is the maximum of a set of linear functions (true even when $f$ is not submodular or $P$ is not a convex set).
An extension of $f$

- Recall, for any such $w \in \mathbb{R}^E$, we have

\[
\begin{pmatrix}
  w_1 \\
  w_2 \\
  \vdots \\
  w_n
\end{pmatrix}
= \left( w_1 - w_2 \right) \begin{pmatrix} 1 & 0 & \cdots & 0 \end{pmatrix}
+ \left( w_2 - w_3 \right) \begin{pmatrix} 0 & 1 & \cdots & 0 \end{pmatrix}
+ \cdots
+ \left( w_{n-1} - w_n \right) \begin{pmatrix} \lambda_{m-1} & 1 & \cdots & 0 \end{pmatrix}
+ \left( w_n \right) \begin{pmatrix} \lambda_m & 1 & \cdots & 1 \end{pmatrix}
\]

(18.23)

- If we take $w$ in decreasing order, then each coefficient of the vectors is non-negative (except possibly the last one, $\lambda_m = w_m$).

Define sets $E_i$ based on this decreasing order of $w$ as follows, for $i = 0, \ldots, n$

\[
E_i \overset{\text{def}}{=} \{ e_1, e_2, \ldots, e_i \}
\]

(18.24)

Note that

\[
1_{E_0} = \begin{pmatrix}
  0 \\
  0 \\
  \vdots \\
  0
\end{pmatrix},
1_{E_1} = \begin{pmatrix} 1 \\
  0 \\
  \vdots \\
  0 \end{pmatrix},
\ldots,
1_{E_\ell} = \begin{pmatrix} 1 & 1 & \cdots & 0 \\
  1 & \vdots & \ddots & 0 \\
  \vdots & \ddots & \ddots & \vdots \\
  0 & \cdots & \cdots & 1 \end{pmatrix},
\ldots
\]

(\ell \times)

\[
(n - \ell \times)
\]

Hence, from the previous and current slide, we have

\[
w = \sum_{i=1}^{m} \lambda_i 1_{E_i}
\]
From $\bar{f}$ back to $f$, even when $f$ is not submodular

- From the continuous $\bar{f}$, we can recover $f(A)$ for any $A \subseteq V$.
- Take $w = 1_A$ for some $A \subseteq E$, so $w$ is vertex of the hypercube.
- Order the elements of $E$ in decreasing order of $w$ so that $w(e_1) \geq w(e_2) \geq w(e_3) \geq \cdots \geq w(e_m)$.
- This means $w = (w(e_1), w(e_2), \ldots, w(e_m)) = (1, 1, 1, \ldots, 1, 0, 0, \ldots, 0)$ \[ (18.25) \]
  so that $1_A(i) = 1$ if $i \leq |A|$, and $1_A(i) = 0$ otherwise.
- For any $f : 2^E \to \mathbb{R}$, $w = 1_A$, since $E_{|A|} = \{e_1, e_2, \ldots, e_{|A|}\} = A$:
  \[
  \bar{f}(w) = \sum_{i=1}^{m} \lambda_i f(E_i) = w(e_m) f(E_m) + \sum_{i=1}^{m-1} (w(e_i) - w(e_{i+1}) f(E_i)
  \]
  \[
  = 1_A(m) f(E_m) + \sum_{i=1}^{m-1} (1_A(i) - 1_A(i+1)) f(E_i)
  \]
  \[
  = (1_A(|A|) - 1_A(|A| + 1)) f(E_{|A|}) = f(E_{|A|}) = f(A)
  \] \[ (18.26) \]

We can view $\bar{f} : [0, 1]^E \to \mathbb{R}$ defined on the hypercube, with $f$ defined as $\bar{f}$ evaluated on the hypercube extreme points (vertices).
- To summarize, with $\bar{f}(A) = \sum_{i=1}^{m} \lambda_i f(E_i)$, we have
  \[
  \bar{f}(1_A) = f(A),
  \] \[ (18.28) \]
- ... and when $f$ is submodular, we also have have
  \[
  \bar{f}(1_A) = \max \{1_A^T x : x \in B_f\}
  \]
  \[
  = \max \{1_A^T x : x(B) \leq f(B), \forall B \subseteq E\}
  \] \[ (18.29) \]
  \[ (18.30) \]
- Note when considering only $\bar{f} : [0, 1]^E \to \mathbb{R}$, then any $w \in [0, 1]^E$ is in positive orthant, adn we have
  \[
  \bar{f}(w) = \max \{w^T x : x \in P_f\}
  \] \[ (18.31) \]
  \[ (18.32) \]
An extension of an arbitrary $f : 2^V \rightarrow \mathbb{R}$

Thus, for any $f : 2^E \rightarrow \mathbb{R}$, even non-submodular $f$, we can define an extension, having $\tilde{f}(1_A) = f(A), \forall A$, in this way where

$$\tilde{f}(w) = \sum_{i=1}^{m} \lambda_i f(E_i) \quad (18.33)$$

with the $E_i = \{e_1, \ldots, e_i\}$'s defined based on sorted descending order of $w$ as in $w(e_1) \geq w(e_2) \geq \cdots \geq w(e_m)$, and where

for $i \in \{1, \ldots, m\}$,  
$$\lambda_i = \begin{cases} w(e_i) - w(e_{i+1}) & \text{if } i < m \\ w(e_m) & \text{if } i = m \end{cases} \quad (18.34)$$

so that $w = \sum_{i=1}^{m} \lambda_i 1_{E_i}$.

$w = \sum_{i=1}^{m} \lambda_i 1_{E_i}$ is an interpolation of certain hypercube vertices.

$\tilde{f}(w) = \sum_{i=1}^{m} \lambda_i f(E_i)$ is the associated interpolation of the values of $f$ at sets corresponding to each hypercube vertex.

Weighted gains vs. weighted functions

Again sorting $E$ descending in $w$, the extension summarized:

$$\tilde{f}(w) = \sum_{i=1}^{m} w(e_i) f(e_i | E_{i-1}) \quad (18.35)$$

$$= \sum_{i=1}^{m} \sum_{j=1}^{m} w(e_i)(f(E_i) - f(E_{i-1})) \quad (18.36)$$

$$= w(e_m) f(E_m) + \sum_{i=1}^{m-1} (w(e_i) - w(e_{i+1})) f(E_i) \quad (18.37)$$

$$= \sum_{i=1}^{m} \lambda_i f(E_i) \quad (18.38)$$

So $\tilde{f}(w)$ seen either as sum of weighted gain evaluations (Eqn. (18.35)), or as sum of weighted function evaluations (Eqn. (18.38)).
Summary: comparison of the two extension forms

- So if \( f \) is submodular, then we can write \( \tilde{f}(w) = \max(wx : x \in P_f) \) (which is clearly convex) in the form:

\[
\tilde{f}(w) = \max(wx : x \in P_f) = \sum_{i=1}^{m} \lambda_i f(E_i) \tag{18.39}
\]

where \( w = \sum_{i=1}^{m} \lambda_i 1_{E_i} \) and \( E_i = \{e_1, \ldots, e_i\} \) defined based on sorted descending order \( w(e_1) \geq w(e_2) \geq \cdots \geq w(e_m) \).

- On the other hand, for any \( f \) (even non-submodular), we can produce an extension \( \tilde{f} \) having the form

\[
\tilde{f}(w) = \sum_{i=1}^{m} \lambda_i f(E_i) \tag{18.40}
\]

where \( w = \sum_{i=1}^{m} \lambda_i 1_{E_i} \) and \( E_i = \{e_1, \ldots, e_i\} \) defined based on sorted descending order \( w(e_1) \geq w(e_2) \geq \cdots \geq w(e_m) \).

- In both Eq. (18.39) and Eq. (18.40), we have \( \tilde{f}(1_A) = f(A) \), \( \forall A \), but Eq. (18.40), might not be convex.

- Submodularity is sufficient for convexity, but is it necessary?

The Lovász extension of \( f : 2^E \to \mathbb{R} \)

- Lovász showed that if a function \( \tilde{f}(w) \) defined as in Eqn. (18.33) is convex, then \( f \) must be submodular.

- This continuous extension \( \tilde{f} \) of \( f \), in any case (\( f \) being submodular or not), is called the Lovász extension of \( f \).

- Note, also possible to define this when \( f(\emptyset) \neq 0 \) (but doesn’t really add any generality).
Proof that min-norm gives optimal Lovász extension

Choquet Integration

Lovász Extension, Submodularity and Convexity

Theorem 18.4.1

A function \( f : 2^E \to \mathbb{R} \) is submodular iff its Lovász extension \( \tilde{f} \) of \( f \) is convex.

Proof.

- We’ve already seen that if \( f \) is submodular, its extension can be written via Eqn.(18.33) due to the greedy algorithm, and therefore is also equivalent to \( \tilde{f}(w) = \max \{wx : x \in P_f\} \), and thus is convex.

- Conversely, suppose the Lovász extension \( \tilde{f}(w) = \sum \lambda_i f(E_i) \) of some function \( f : 2^E \to \mathbb{R} \) is a convex function.

We note that, based on the extension definition, in particular the definition of the \( \{\lambda_i\}_i \), we have that \( \tilde{f}(\alpha w) = \alpha \tilde{f}(w) \) for any \( \alpha \in \mathbb{R}_+ \). I.e., \( f \) is a positively homogeneous convex function.

...
Proof that min-norm gives optimal Lovász extension

Also, since $\tilde{f}$ is convex (by assumption) and positively homogeneous, we have for any $A, B \subseteq E$,

$$0.5[f(A \cap B) + f(A \cup B)] = 0.5[\tilde{f}(1_A + 1_B)] = \tilde{f}(0.51_A + 0.51_B) \leq 0.5\tilde{f}(1_A) + 0.5\tilde{f}(1_B) = 0.5(f(A) + f(B))$$ (18.45)

Thus, we have shown that for any $A, B \subseteq E$,

$$f(A \cup B) + f(A \cap B) \leq f(A) + f(B)$$ (18.49)

so $f$ must be submodular.

Edmonds - Submodularity - 1969

SUBMODULAR FUNCTIONS, MATROIDS, AND CERTAIN POLYHEDRA*

Jack Edmonds

I.

The viewpoint of the subject of matroids, and related areas of lattice theory, has always been, in one way or another, abstraction of algebraic dependence or, equivalently, abstraction of the incidence relations in geometric representations of algebra. Often one of the
Submodular functions and convexity

L. Lovász
Eötvös Loránd University, Department of Analysis I, Múzeum krt. 6-8, H-1088 Budapest, Hungary

0. Introduction

In “continuous” optimization convex functions play a central role. Besides elementary tools like differentiation, various methods for finding the minimum of a convex function constitute the main body of nonlinear optimization. But even linear programming may be viewed as the optimization of very special (linear) objective functions over very special convex domains (polyhedra). There are several reasons for this popularity of convex functions:

- Convex functions occur in many mathematical models in economy, engineering, and other sciences. Convexity is a very natural property of various functions and domains occurring in such models; quite often the only non-trivial property which can be stated in general.

Integration and Aggregation

- Integration is just summation (e.g., the $\int$ symbol has as its origins a sum).
- Lebesgue integration allows integration w.r.t. an underlying measure $\mu$ of sets. E.g., given measurable function $f$, we can define

$$\int_X f du = \sup I_X(s) \quad (18.50)$$

where $I_X(s) = \sum_{i=1}^{n} c_i \mu(X \cap X_i)$, and where we take the $\sup$ over all measurable functions $s$ such that $0 \leq s \leq f$ and $s(x) = \sum_{i=1}^{n} c_i I_{X_i}(x)$ and where $I_{X_i}(x)$ is indicator of membership of set $X_i$, with $c_i > 0$. 
Integration, Aggregation, and Weighted Averages

- In finite discrete spaces, Lebesgue integration is just a weighted average, and can be seen as an aggregation function.
- I.e., given a weight vector $w \in [0, 1]^E$ for some finite ground set $E$, then for any $x \in \mathbb{R}^E$ we have the weighted average of $x$ as:

$$\text{WAVG}(x) = \sum_{e \in E} x(e)w(e) \quad (18.51)$$

- Consider $1_e$ for $e \in E$, we have

$$\text{WAVG}(1_e) = w(e) \quad (18.52)$$

so seen as a function on the hypercube vertices, the entire WAVG function is given based on values on a size $m = |E|$ subset of the vertices of this hypercube, i.e., $\{1_e : e \in E\}$. Moreover, we are interpolating as in

$$\text{WAVG}(x) = \sum_{e \in E} x(e)w(e) = \sum_{e \in E} x(e)\text{WAVG}(1_e) \quad (18.53)$$

- Clearly, WAVG function is linear in weights $w$, in the argument $x$, and is homogeneous. That is, for all $w, w_1, w_2, x, x_1, x_2 \in \mathbb{R}^E$ and $\alpha \in \mathbb{R},$

$$\text{WAVG}_{w_1+w_2}(x) = \text{WAVG}_{w_1}(x) + \text{WAVG}_{w_2}(x), \quad (18.55)$$
$$\text{WAVG}_{w}(x_1 + x_2) = \text{WAVG}_{w}(x_1) + \text{WAVG}_{w}(x_2), \quad (18.56)$$

and,

$$\text{WAVG}(\alpha x) = \alpha \text{WAVG}(x). \quad (18.57)$$

- We will see: The Lovász extension is still be linear in “weights” (i.e., the submodular function $f$), but will not be linear in $x$ and will only be positively homogeneous (for $\alpha \geq 0$).
More complex “nonlinear” aggregation functions can be constructed by defining the aggregation function on all vertices of the hypercube. I.e., for each $1_A : A \subseteq E$ we might have (for all $A \subseteq E$):

$$\text{AG}(1_A) = w_A$$ (18.58)

What then might $\text{AG}(x)$ be for some $x \in \mathbb{R}^E$? Our weighted average functions might look something more like the r.h.s. in:

$$\text{AG}(x) = \sum_{A \subseteq E} x(A)w_A = \sum_{A \subseteq E} x(A)\text{AG}(1_A)$$ (18.59)

Note, we can define $w(e) = w'(e)$ and $w(A) = 0, \forall A : |A| > 1$ and get back previous (normal) weighted average, in that

$$\text{WAVG}_{w'}(x) = \text{AG}_w(x)$$ (18.60)

Set function $f : 2^E \rightarrow \mathbb{R}$ is a game if $f$ is normalized $f(\emptyset) = 0$.

Set function $f : 2^E \rightarrow \mathbb{R}$ is called a capacity if it is monotone non-decreasing, i.e., $f(A) \leq f(B)$ whenever $A \subseteq B$.

A Boolean function $f$ is any function $f : \{0, 1\}^m \rightarrow \{0, 1\}$ and is a pseudo-Boolean function if $f : \{0, 1\}^m \rightarrow \mathbb{R}$.

Any set function corresponds to a pseudo-Boolean function. I.e., given $f : 2^E \rightarrow \mathbb{R}$, form $f_b : \{0, 1\}^m \rightarrow \mathbb{R}$ as $f_b(x) = f(A_x)$ where the $A, x$ bijection is $A = \{e \in E : x_e = 1\}$ and $x = 1_A$.

Also, if we have an expression for $f_b$ we can construct a set function $f$ as $f(A) = f_b(1_A)$. We can also often relax $f_b$ to any $x \in [0, 1]^m$.

We saw this for Lovász extension.

It turns out that a concept essentially identical to the Lovász extension was derived much earlier, in 1954, and using this derivation (via integration) leads to deeper intuition.
Definition 18.5.1

Let $f$ be any capacity on $E$ and $w \in \mathbb{R}_+^E$. The Choquet integral (1954) of $w$ w.r.t. $f$ is defined by

$$C_f(w) = \sum_{i=1}^{m} (w_{e_i} - w_{e_{i+1}}) f(E_i) \quad (18.61)$$

where in the sum, we have sorted and renamed the elements of $E$ so that $w_{e_1} \geq w_{e_2} \geq \cdots \geq w_{e_m} \geq w_{e_{m+1}} \triangleq 0$, and where $E_i = \{e_1, e_2, \ldots, e_i\}$.

We immediately see that an equivalent formula is as follows:

$$C_f(w) = \sum_{i=1}^{m} w(e_i)(f(E_i) - f(E_{i-1})) \quad (18.62)$$

where $E_0 \triangleq \emptyset$.

BTW: this again essentially Abel’s partial summation formula: Given two arbitrary sequences $\{a_n\}$ and $\{b_n\}$ with $A_n = \sum_{k=1}^{n} a_k$, we have

$$\sum_{k=m}^{n} a_k b_k = \sum_{k=m}^{n} A_k (b_k - b_{k+1}) + A_n b_{n+1} - A_{m-1} b_m \quad (18.63)$$
Proof that min-norm gives optimal Lovász extension

The "integral" in the Choquet integral

- Thought of as an integral over $\mathbb{R}$ of a piece-wise constant function.
- First note, assuming $E$ is ordered according to descending $w$, so that $w(e_1) \geq w(e_2) \geq \cdots \geq w(e_{m-1}) \geq w(e_m)$, then $E_i = \{e_1, e_2, \ldots, e_i\} = \{e \in E : w_e \geq w_{e_i}\}$.
- For any $w_{e_i} > \alpha \geq w_{e_{i+1}}$ we also have $E_i = \{e_1, e_2, \ldots, e_i\} = \{e \in E : w_e > \alpha\}$.
- Consider segmenting the real-axis at boundary points $w_{e_i}$, right most is $w_{e_1}$.

<table>
<thead>
<tr>
<th>$w(e_m)$</th>
<th>$w(e_{m-1})$</th>
<th>$\cdots$</th>
<th>$w(e_5)$</th>
<th>$w(e_4)$</th>
<th>$w(e_3)$</th>
<th>$w(e_2)$</th>
<th>$w(e_1)$</th>
</tr>
</thead>
</table>

- A function can be defined on a segment of $\mathbb{R}$, namely $w_{e_i} > \alpha \geq w_{e_{i+1}}$. This function $F_i : [w_{e_{i+1}}, w_{e_i}) \rightarrow \mathbb{R}$ is defined as
  \[ F_i(\alpha) = f(\{e \in E : w_e > \alpha\}) = f(E_i) \]  
  (18.64)

Note, what is depicted may be a game but not a capacity. Why?
Now consider the integral, with \( w \in \mathbb{R}^E_+ \), and normalized \( f \) so that \( f(\emptyset) = 0 \). Recall \( w_{m+1} \equiv 0 \).

\[
\tilde{f}(w) \overset{\text{def}}{=} \int_0^\infty F(\alpha)\,d\alpha \quad (18.65)
\]

\[
= \int_0^\infty f(\{e \in E : w_e > \alpha\})\,d\alpha \quad (18.66)
\]

\[
= \int_{w_{m+1}}^\infty f(\{e \in E : w_e > \alpha\})\,d\alpha \quad (18.67)
\]

\[
= \sum_{i=1}^m \int_{w_{i+1}}^{w_i} f(\{e \in E : w_e > \alpha\})\,d\alpha \quad (18.68)
\]

\[
= \sum_{i=1}^m \int_{w_{i+1}}^{w_i} f(E_i)\,d\alpha = \sum_{i=1}^m f(E_i)(w_i - w_{i+1}) \quad (18.69)
\]

But we saw before that \( \sum_{i=1}^m f(E_i)(w_i - w_{i+1}) \) is just the Lovász extension of a function \( f \).

Thus, we have the following definition:

**Definition 18.5.2**

Given \( w \in \mathbb{R}^E_+ \), the Lovász extension (equivalently Choquet integral) may be defined as follows:

\[
\tilde{f}(w) \overset{\text{def}}{=} \int_0^\infty F(\alpha)\,d\alpha \quad (18.70)
\]

where the function \( F \) is defined as before.

Note that it is not necessary in general to require \( w \in \mathbb{R}^E_+ \) (i.e., we can take \( w \in \mathbb{R}^E \)) nor that \( f \) be non-negative, but it is a bit more involved. Above is the simple case.

The above integral will be further generalized a bit later.
Recall, we want to produce some notion of generalized aggregation function having the flavor of:

$$\text{AG}(x) = \sum_{A \subseteq E} x(A)w_A = \sum_{A \subseteq E} x(A)\text{AG}(1_A)$$ \hspace{1cm} (18.71)

how does this correspond to Lovász extension?

Let us partition the hypercube $[0, 1]^m$ into $q$ polytopes, each defined by a set of vertices $V_1, V_2, \ldots, V_q$.

E.g., for each $i$, $V_i = \{1_{A_1}, 1_{A_2}, \ldots, 1_{A_k}\}$ ($k$ vertices) and the convex hull of $V_i$ defines the $i$th polytope.

This forms a “triangulation” of the hypercube.

For any $x \in [0, 1]^m$ there is a (not necessarily unique) $\mathcal{V}(x) = V_j$ for some $j$ such that $x \in \text{conv}(\mathcal{V}(x))$.

Most generally, for $x \in [0, 1]^m$, let us define the (unique) coefficients $\alpha^x_0(A)$ and $\alpha^x_i(A)$ that define the affine transformation of the coefficients of $x$ to be used with the particular hypercube vertex $1_A \in \text{conv}(\mathcal{V}(x))$. The affine transformation is as follows:

$$\alpha^x_0(A) + \sum_{j=1}^m \alpha^x_j(A)x_j \in \mathbb{R}$$ \hspace{1cm} (18.72)

Note that many of these coefficient are often zero.

From this, we can define an aggregation function of the form

$$\text{AG}(x) \overset{\text{def}}{=} \sum_{A:1_A \in \mathcal{V}(x)} \left(\alpha^x_0(A) + \sum_{j=1}^m \alpha^x_j(A)x_j\right)\text{AG}(1_A)$$ \hspace{1cm} (18.73)
We can define a canonical triangulation of the hypercube in terms of
permutations of the coordinates. I.e., given some permutation \( \sigma \), define
\[
\text{conv}(\mathcal{V}_\sigma) = \{ x \in [0, 1]^n | x_{\sigma(1)} \geq x_{\sigma(2)} \geq \cdots \geq x_{\sigma(m)} \} \quad (18.74)
\]
Then these \( m! \) blocks of the partition are called the canonical
partitions of the hypercube.

With this, we can define \( \{V_i\}_i \) as the vertices of \( \text{conv}(\mathcal{V}_\sigma) \) for each
permutation \( \sigma \). In this case, we have:

**Proposition 18.5.3**

The above linear interpolation in Eqn. (18.73) using the canonical partition
yields the Lovász extension with \( \alpha_0^x(A) + \sum_{j=1}^{m} \alpha_j^x(A)x_j = x_{\sigma_i} - x_{\sigma_{i-1}} \) for
\( A = E_i = \{e_{\sigma_1}, \ldots, e_{\sigma_i}\} \) for appropriate order \( \sigma \).

Hence, Lovász extension is a generalized aggregation function.
